

Step by Step Process

First I created a dynamic web project and created an xml descriptor. Next I created an html file and added a form for the user to input a username along with a button to execute a get request. Then I created 3 servlets; one to login, one to logout, and one to display information on the dashboard. The login servlet sets the user ID attribute with the username once the button is pressed and redirects to the dashboard. The dashboard checks if the username is valid and then prints out that the user successfully logged in. If it is invalid then it prints an error message. After logging in the user is prompted to logout.

I added a table on the index page to display all the valid usernames for ease of testing.
